Reference: “Object Oriented Programming Specialization: Build a Crypto-Trading Platform with C++”, Professor Matthew Yee-King, University of London.	
1. The Wallet	(A) The wallet is where we are going to keep all of the coins we're buying and selling on the platform. (B) It contains a variety of different currencies (C) Over time we're going to sell and buy different currencies from our wallet. Step 1: To initialize the wallet. - Get some currency - Put it into the wallet. - Start off with a kind of fund with which we can then start trading. Step 2: To place a bid. - A bid = an offer to buy something. - A bid = “I would like to buy this much of this currency in exchange for this currency.” - When placing a bid, we're need to check that the wallet contains enough of the currency we're offering to buy with to cover the sale if it goes ahead. Step 3: Once we've collected some currency is to sell something. - In this case we offer to sell something for a certain amount of something else. - We need to make sure that the wallet contains sufficient currency to cover that sale so that we actually own the thing we're trying to sell. - In order to maintain the state of the wallet, money is going to come in and money's going to come out in different currencies. - So over time the contents of the wallet will change.
